KANTEC CONTINUUM · PLATFORM ENGINEERING

WHY IBM WEBMETHODS

Hybrid integration you can govern — applications, APIs, events, B2B and agents on one control plane.

Connect what the enterprise already runs. Control how AI is allowed to act on it.

There is a growing problem inside almost every enterprise.

Boards are setting policies for application modernisation, API exposure, B2B partner exchange, data residency and now agentic AI. The work that actually implements those policies is integration: the flows, APIs, events, files and partner connections that move a transaction from one system of record to another.

Yet most estates still look like this:

- A cloud iPaaS for new SaaS connections — and a separate on-premises ESB for everything that cannot leave the data centre.
- An API gateway that does not share catalogue, policy or identity with the integration runtime.
- B2B/EDI and managed file transfer treated as a specialist island.
- AI agents given tools and credentials without the same governance applied to enterprise APIs.

IBM webMethods — now the core of IBM's hybrid integration portfolio, including IBM Integration SaaS (formerly IBM webMethods Hybrid Integration) — is designed to close that gap.

The question for executives is therefore changing from:

> *"Do we have an integration tool?"*

to:

> *"Can we continuously demonstrate that applications, partners, APIs and AI agents connect only through governed paths — across cloud and on-premises — and that those paths operate within policy?"*

That distinction sits at the heart of Why IBM webMethods.

A Simple Idea

IBM webMethods is a unified hybrid integration platform: application integration, API management, events, B2B/EDI, managed file transfer and, increasingly, governed access for AI agents and large language models — under one control plane that can span SaaS and software deployments.

IBM acquired webMethods from Software AG and has been folding it into the wider IBM Integration portfolio (alongside App Connect, API Connect and related capabilities). The executive point is not the brand chronology. It is the operating model: one place to design, run, observe and govern the connections the business depends on.

The result is not another connector catalogue. It is an ability to answer a much more important question:

Is the organisation operating integration within the controls it approved — including for AI — and can it prove it?

Why This Becomes Particularly Important With AI

Consider a Board that approves an AI, data and integration policy. It may specify approved systems of record, partner channels, API standards, residency rules and oversight for agents that can call enterprise tools.

The policy may be excellent. But the CIO should ask:

"How do we know?"

How do we know a new SaaS or partner connection did not bypass the approved integration path?

How do we know APIs exposed to partners or to AI agents carry the same identity, rate and data policies?

How do we know B2B and file exchanges still meet contractual and regulatory obligations?

How do we know an agent is using Model Context Protocol tools that map to governed APIs rather than unmanaged credentials?

How do we know we can show a regulator or customer the path a transaction actually took?

This is no longer simply a middleware question. It is a governance question.

From Point-to-Point Integration to Continuous Assurance

The traditional model effectively asks:

"Did the interface work when we last tested it?"

Hybrid integration asks:

"Are connections operating within policy now — across apps, APIs, events, partners and agents — and where are the exceptions?"

Traditional integration practice	IBM webMethods / IBM Integration
Separate ESB, iPaaS, API gateway and B2B stack	**Unified hybrid control plane across styles and placements**
Cloud-only iPaaS that stops at the data-centre wall	**SaaS and software options for on-prem, hybrid and sovereign needs**
APIs unmanaged, or managed in a different product silo	**API management in the same portfolio as the flows that implement them**
EDI / MFT as a specialist leftover	**B2B and file exchange as first-class integration capabilities**
AI agents given raw credentials and tools	**Governed AI interactions via enterprise APIs, MCP-style tools and policy**
"We have middleware"	**"We can demonstrate control of the connection fabric"**

The objective is not to eliminate every specialist tool. It is to give the enterprise a governed backbone for the connections that matter — and better evidence for the tools that remain.

The Board and Executive Conversation

Imagine replacing a long integration landscape slide with five questions.

1. **Are we operating integration within agreed risk, residency and partner-contract boundaries?**
2. **Which critical connections still sit outside the governed platform?**
3. **Where is our greatest exposure — APIs, B2B, events, files or unmanaged AI tools?**

4. **Are the controls designed for those paths actually working?**
5. **What requires an executive decision on consolidation versus tolerated exception?**

That is Why IBM webMethods at executive level. The technology underneath becomes largely invisible.

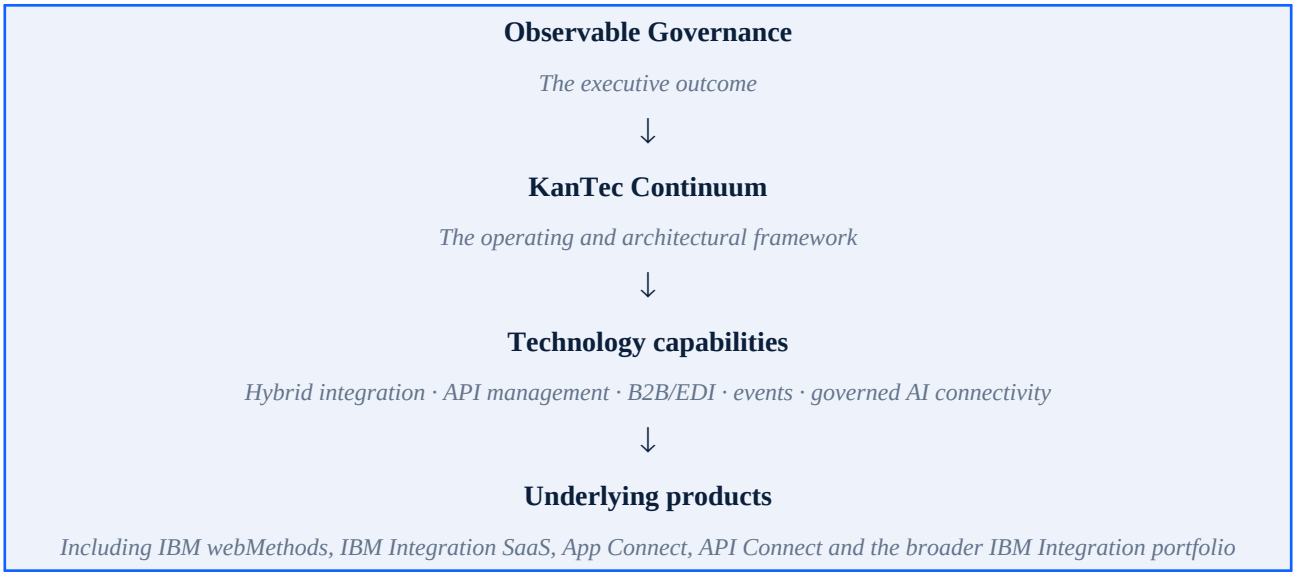
Executives see risk, evidence, accountability and decisions.

Where KanTec Fits

KanTec helps organisations make governance observable — including the integration fabric that every application, partner and AI agent depends on.

KanTec Continuum is the enabling framework connecting governance intent with the technologies the organisation depends on. IBM webMethods / IBM Integration is a foundational capability within that stack: hybrid integration that can turn connection policy into continuous, observable paths.

The hierarchy becomes:



Questions CIOs should consider:

> *"You have delegated application, partner and AI connectivity throughout the organisation. How do you know those connections still run through the paths you approved?"*

> *"What evidence reaches you today — beyond a list of interfaces and an uptime chart?"*

> *"If an agent, a partner or a shadow flow opens a path outside policy, how quickly would you know?"*

This is Why IBM webMethods — Observable Governance for the connection fabric.

The CISO / Risk Conversation

> *"Can you demonstrate control effectiveness on APIs, partners and AI tools — rather than simply show that a gateway and an iPaaS exist?"*

A policy might state that production APIs must be authenticated, that partner EDI follows an approved map, or that agents may only invoke published tools. Observable Governance should connect:

Policy → connection / API / partner / agent tool → actual runtime path → business context → exception → evidence

The outcome is not simply an interface count. It is an answer to: “Are we within risk appetite?”

The AI / Agentic Conversation

IBM’s current webMethods / Integration positioning treats agents and LLMs as first-class consumers of the integration fabric — including governed access to enterprise APIs and MCP-style tools rather than unmanaged side channels.

> *“How many agents can already call systems of record — and through which ungoverned tools?”*
>
> *“How would we prove tomorrow that an agent used an approved API rather than a copied credential?”*
>
> *“Can we reuse the integration estate we already paid for, instead of building a parallel AI connectivity layer?”*

That is hybrid integration as an Observable AI architecture, not as a point-to-point connector project.

The Real Product Is Confidence

Boards don’t really want another ESB. They don’t particularly want more interface inventories. They certainly don’t want more ungoverned agents. They want confidence.

Confidence that:

- systems of record are reached through approved paths;
- APIs, events, files and B2B share one governance story;
- hybrid and sovereign placements are possible without a second toolchain;
- exceptions are visible;
- someone is accountable;
- AI agents inherit enterprise policy instead of bypassing it;
- management can demonstrate all of the above.

Why IBM webMethods turns that confidence from an assumption into a governed integration platform.

The KanTec Executive Proposition

Governing thought

In a continuously changing application and AI environment, integration governance can no longer be a project. It must become observable — from partner and API to agent and runtime.

1. Connections change continuously. Point-to-point maps and annual interface reviews cannot provide continuous confidence.

2. Governance establishes what should happen. Risk appetite, API and partner policies establish management intent.

3. A hybrid integration platform establishes what is happening. Flows, APIs, events and agent tools generate evidence of actual paths.

4. Observable Governance connects the two. It identifies the gap between intent and the connections actually running.

5. Management can then act. Exceptions become visible, ownership becomes clear and remediation can itself be evidenced.

Which gives KanTec a very simple executive story:

Govern → Connect → Observe → Prove → Improve

Executive Summary

If you were sitting opposite a CEO, CIO or CISO, I would say:

> *"Every organisation has integration. The problem is that governance tells you how systems should connect, while the estate is usually a mix of cloud iPaaS, leftover ESBs, a separate API gateway and a growing set of AI tools."*
>
> *"We call the connection Observable Governance. For integration, that means a hybrid platform: one control plane for apps, APIs, events, B2B and the agents that will call them."*
>
> *"IBM webMethods — in the IBM Integration portfolio — is built around that idea, including SaaS and software placements, so management can ask whether policy is working today, not only whether an interface was signed off last year."*
>
> *"KanTec Continuum provides the architecture that connects those layers — including IBM webMethods as a foundational capability."*

Govern from the top. Connect through the platform. Prove continuously.

Why IBM webMethods

Know that integration policy is operating. Prove it across apps, APIs, partners and agents.

KanTec connects executive intent with operational reality — turning hybrid integration into something you can govern and continuously evidence.

This document is based on publicly available information from IBM and is intended as a KanTec Continuum executive briefing. IBM is phasing portfolio names: IBM Integration SaaS was formerly IBM webMethods Hybrid Integration; related capabilities include App Connect and API Connect. Product names, deployment options and claims are subject to configuration and change; consult IBM and KanTec for current details.
